㉓ Ziegler type catalyst system.

㉔ A Ziegler type catalyst system for alpha-olefin type polymerization which includes R<sub>3</sub>Y, R<sub>2</sub>'YX or a mixture thereof, at least one supported Group IVA-VIII transition metal halide and an alkyl metal compound selected from R<sub>2</sub>'YNR<sub>2</sub> and R'XYNR<sub>2</sub>, wherein Y is Al, Ga or In. The improved catalyst system provides increased polymerization activity without significantly affecting the crystallinity of the polymer.

EP 0015763 A1

1

2       The present           invention relates to  
3       improved Ziegler type catalyst systems for the conven-  
4       tional alpha-olefin type polymerizations thereby yielding  
5       polymers having a high degree of isotactic stereoregularity.

6       An object of the present invention is to provide im-  
7       proved Ziegler type catalyst systems having a major increase  
8       in polymerization activity while being able to control the  
9       polymer crystallinity over a wide range, e.g., isotacticity,  
10      wherein the catalyst system includes at least one Group  
11      IVA-VIII transition metal halide, an alkyl metal cocatalyst  
12      selected from the group consisting of  $R'_3Y$  or  $R'_2YX$  and mix-  
13      tures thereof and an alkyl metal compound being selected  
14      from  $R'_2YNR$  and  $R'XYNR_2$ , wherein  $R'$  is selected from the  
15      group consisting of  $C_1$  to  $C_{20}$  primary alkyl, secondary alkyl,  
16      tertiary alkyl, neopentyl alkyl, branched alkyl, naphtenic,  
17      or aralkyl groups, X is a halide group, R is selected from  
18      the group consisting of  $C_3$  to  $C_{20}$  bulky alkyl groups,  
19      cycloalkyl groups, aryl groups, or a cyclic amine structure,  
20      and Y is selected from the group consisting of aluminum,  
21      gallium and indium.

22      A further object of the present invention is to provide  
23      an improved process for alpha-olefin type polymerizations,  
24      wherein the polymerization activity is increased without  
25      adversely affecting the crystallinity of the formed polymer.

26      A still further object of the present invention is to  
27      provide an improved Ziegler type catalyst system wherein  
28      Catalyst poisons are consumed in situ thereby minimizing the

1 formation of atactic type polymers wherein the catalyst  
2 poison  $R'AlX_2$  is effectively removed from the catalyst  
3 thereby making a higher number of active sites.

4 A still further object is the advantage over the  
5 alternative catalysts of being able to use the present compounds  
6 directly with any type of transition metal halide without modi-  
7 fication of the commercial catalyst preparation or the polymeri-  
8 zation plant.

9

10 During a Ziegler type alpha-olefin polymerization  
11 which employs  $TiCl_3$  in combination with  $R'_3Y$  or  $R'_2YX$ , the by-  
12 product  $R'YX_2$  is formed on the surface of the  $TiCl_3$  thereby  
13 acting as a catalyst poison (deactivator), wherein  $R'$  is selected  
14 from the group consisting of  $C_1$  to  $C_{20}$  primary alkyl, secondary  
15 alkyl, tertiary alkyl, neopentyl alkyl, branched  
16 alkyl, naphthenic or aralkyl groups, preferably a  $C_2$  to  $C_4$   
17 alkyl group,  $X$  is a halide group,  $Y$  is selected from the group  
18 consisting of Al, Ga or In.

19 It has been shown that the addition of small amounts  
20 of  $EtAlCl_2$  to a  $TiCl_3-Et_2AlCl$  catalyst system dramatically  
21 reduces polymerization rates (Ingberman, et. al., J. Polymer  
22 Sci. A4, 2781 (1966)). Since the formation of an active cat-  
23 alyst site during polymerization involves the reaction  $R'_2AlCl$   
24 +  $TiCl_3 \longrightarrow R'AlCl_2 + R'TiCl_2$  on the surface of the  $TiCl_3$   
25 crystal, it is apparent that the  $R'AlCl_2$  catalyst poison (or  
26 deactivator) is always present in such catalyst systems.

27 Likewise for the reaction of  $R'_3Al$  with excess  $TiCl_3$  is:  
28  $R'_3Al + TiCl_3$  (excess)  $\longrightarrow R'AlCl_2 + R'_2AlCl + 3R'TiCl_2(TiCl_3)_x$

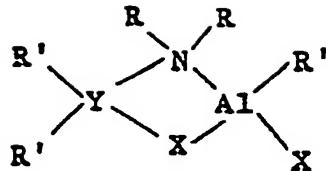

29 It has been surprisingly found that this catalyst  
30 poison  $R'AlX_2$  can be effectively removed from the surface of  
31 the  $TiCl_3$  by the addition of a compound  $R'_2YNR_2$  or  $R'XNR_2$  to  
32 the  $TiCl_3-R'_3Al$  or  $TiCl_3-R'_2AlX$ . The  $R'_2YNR_2$  reacts selec-  
33 tively with  $R'AlX_2$  in two different ways either to remove the  
34  $R'AlX_2$  by the formation of mixed dimers:

1

2

3

4

5 or by transalkylation to regenerate  $R'_2AlX$  and to generate  
 6  $R'XYNR_2$ :  $R'_2YNR_2 + R'AlX_2 \longrightarrow R'XYNR_2 + R'_2AlX$ . In the case  
 7 of  $R'XYNR_2$ , the  $R'AlX_2$  is simply removed by formation of a  
 8 catalytically inactive mixed dimer. In either case, the  
 9  $R'AlX_2$  is effectively removed from the catalyst sites, thereby  
 10 resulting in a higher number of active sites per unit of  
 11 catalyst volume which is reflected in a large increase in  
 12 activity. When the amide ( $R'_2YNR_2$ ) of the present  
 13 invention is used in relatively small amounts based on the  
 14  $R'_3Al$  or  $R'_2AlX$ , the polymer isotacticity (as measured by  
 15 heptane insolubles, density, tensile, etc.) is similar to  
 16 or higher than that obtained with either  $R'_3Al$  or  $R'_2AlX$   
 17 alone. When higher proportions are used relative to  $R'_2AlX$   
 18 or  $R'_3Al$ , the polymer becomes less isotactic, but polymeriza-  
 19 tion rates increase to even higher levels. Thus, one can  
 20 achieve remarkable increases in activity from any  $TiCl_3$  or  
 21  $TiCl_4$  catalyst while simultaneously controlling polymer iso-  
 22 tacticity over a wide range. Another advantage the cocatalyst  
 23 supplement of the invention has over alternative catalysts is  
 24 that it may be used directly with any type of  $TiCl_3$  or  $TiCl_4$   
 25 presently being used without modification of the commercial  
 26 catalyst preparation or the polymerization plant.

27 -

The amides usable in the invention have the general  
 28 structures  $R'_2AlNR_2$  and  $R'XAlNR_2$ , wherein  $R' = C_1$  to  $C_{20}$  hydro-  
 29 carbyl group such as primary alkyl, secondary alkyl, tertiary  
 30 alkyl, neopentyl alkyl, branched alkyl, cycloalkyl or aralkyl,  
 31 preferably a  $C_{1-12}$  alkyl; and  $R = C_3$  to  $C_{20}$  bulky alkyl,  
 32 cycloalkyl, aryl or substituted aryl groups, including ring  
 33 structures such as  $R_2Al$  piperidide and  $Et_2Al$  pyrrolidide.  
 34 Hindered amide groups derived from hindered secondary  
 35 amines are especially preferred because they interact  
 36 less strongly with the  $TiCl_3$  and have greater driving

1 force to form mixed dimers with the  $R'AlCl_2$  poison. Such com-  
2 pounds have large, bulky R groups by virtue of branching on  
3 the carbons alpha, beta or gamma to the nitrogen. Illustrative  
4 examples of R groups include isopropyl, isobutyl, neopentyl,  
5 3,3-diethylhexyl, 2-ethylhexyl, 2-butyl, 2-octyl, 3-pentyl,  
6 cyclohexyl, cyclopentyl, 2-methyl-cyclopentyl, 3-ethylcyclohex-  
7 yl, phenyl, totyl, xylyl, chlorophenyl, naphthyl and mixtures  
8 including mixtures in which one R group may be a less bulky  
9 saturated group such as a normal alkyl. Also, the two R  
10 groups may be part of a cyclic amine structure, such as pyrrol-  
11 idyl, piperidyl, and the like and their various alkyl substi-  
12 tuted derivatives especially when the substituents are on the  
13 carbon atoms adjacent to the nitrogen atoms, such as 2,6-diiso-  
14 propylpiperidide, 2,2,6,6-tetramethylpiperidide, and the like.

15 The Y group of  $R''_2YNR_2$  is selected from the group  
16 consisting of aluminum, gallium, or indium, most preferably  
17 aluminum.

18 The ratio of amide to  $TiCl_3$  is between 0.05:1 to  
19 5:1. The lower ratios are used together with "low aluminum"  
20 containing  $TiCl_3$  to make highly isotactic polymers at high  
21 rates. Higher ratios are used with aluminum-containing  $TiCl_3$   
22 catalysts such as the commercial  $TiCl_3 \cdot 0.33 AlCl_3$  catalyst.  
23 "Low-aluminum" containing  $TiCl_3$  refers to  $TiCl_3$  catalysts  
24 which have low Al because of method of formation or have had a  
25 major portion of the aluminum removed as a result of subse-  
26 quent reactions.

27 These new cocatalyst mixtures are useful with any  
28 of the crystal modifications of  $TiX_3$ , with solid solutions of  
29 Groups II-III metal salts in  $TiX_3$  (also referred to as "co-  
30 crystallized" such as  $TiCl_3 \cdot nAlCl_3$  or  $TiCl_3 \cdot nMgCl_2$ , and with  
31  $TiX_3$  or  $TiX_4$  supported on salts such as  $MgCl_2$  or hydroxy-  
32 chloride, oxides or other inorganic or organic supports,  
33 wherein X = Cl or Br, preferably Cl. Lewis bases, alcohols,  
34 carboxylic acids, etc. may also be present. The most pre-  
35 ferred crystal structure is delta or pseudo delta, the latter  
36 being a mixture of disordered, very small alpha and gamma

1 crystallites. This invention is also useful for increasing  
2 the activity and/or stereo-specificity of supported  $TiCl_4$  and  
3  $TiCl_3$ -type catalysts and other supported predominantly tri-  
4 valent titanium compounds. The  $TiCl_3$ -type catalysts may be  
5 prepared from  $TiCl_4$  by any of the reduction and crystalliza-  
6 tion procedures known in the art ( $H_2$ , metal metal hydrides,  
7 alkyl, etc.). Low aluminum  $TiCl_3$  type catalysts are preferred.

8        Lewis bases can be employed in combination with the  
9 trialkyl metal compound or with the Group IVA to VIII transi-  
10 tion metal compound or with both components as long as they  
11 do not cause excessive cleavage of metal-carbon bonds or loss  
12 of active sites. A wide variety of Lewis bases may be used  
13 including such types as tertiary amines, esters, phosphines,  
14 phosphine oxides, phosphates (alkyl, aryl), phosphites, hexa-  
15 alkyl phosphoric triamides, dimethyl sulfoxide, dimethyl for-  
16 mamide, secondary amines, ethers, epoxides, ketones, saturated  
17 and unsaturated heterocycles, or cyclic ethers and mixtures  
18 thereof. Typical but non-limiting examples are diethyl ether,  
19 dibutyl ether, tetrahydrofuran, ethylacetate, methyl p-toluate,  
20 ethyl p-anisate, ethyl benzoate, phenyl acetate, amyl acetate,  
21 methyl octanoate, acetophenone, benzophenone, triethylamine,  
22 tributyl amine, dimethyldecylamine, pyridine, N-methylpiperi-  
23 dine, 2,2,6,6-tetramethylpiperidine, and the like. Especially  
24 useful in combination with the trialkyl metal cocatalyst are  
25 Lewis bases whose complexing ability toward the cocatalyst is  
26 "hindered" sufficiently by steric and/or electronic effects to  
27 cause appreciable dissociation of the trialkyl metal-Lewis  
28 base complex under polymerization conditions. Although a wide  
29 range of mole ratios may be used, dissociation of the complex  
30 as measured on a 1:1 complex is normally in the range of 1-99  
31 mole %, more preferably 5-95%, and most preferably greater  
32 than 10% and less than 90%. Steric hindrance is achieved  
33 by bulky substituents around the heteroatom which reduces  
34 the accessibility of the base functionality to the Lewis  
35 acid, that is, the trialkyl metal compound. Electronic  
36 hindering is obtained by placing electron withdrawing sub-

1 stituents on the heteroatom to reduce the electron density on  
2 basic heteroatom. Aromatic substituents are especially useful  
3 because they are relatively unreactive toward other catalyst  
4 components. Hindered Lewis bases derived from piperidines,  
5 pyrrolidines, ketones, tetrahydrofurans, secondary and tertiary  
6 aromatic amines and tertiary aliphatic amines are preferred,  
7 with the hindered nitrogen bases being most preferred. Non-  
8 limiting examples of sterically hindered bases include  
9 2,2,6,6-tetramethylpiperidine, 2,2,5,5,-tetramethylpyrrolidine,  
10 2,2,5,5,-tetramethyltetrahydrofuran, di-tert-butylketone, 2,6-  
11 diisopropylpiperidine, ortho-tolyl t-butyl ketone, methyl 2,6-  
12 di-tert-butylphenylketone, diisopropylethylamine, t-butyldi-  
13 methylamine, 6-methyl-2-isopropylpyridine, and the like.  
14 Electronically hindered Lewis bases include diphenylamine, di-  
15 ortho-tolylamine, N,N-diethyl-aniline, di-ortho-tolylketone,  
16 and the like. Since aromatic substituents are also bulky, some  
17 of the electronically hindered bases can also have a steric  
18 contribution to the hindrance. Especially preferred hindered  
19 amines are 2,2,6,6-tetramethylpiperidine, 2,2,5,5,-tetramethyl-  
20 pyrrolidine and the diarylamines. Completely hindered bases,  
21 such as 2,6-di-tertiarybutylpyridine, and the like, which  
22 complex the alkyl metal cocatalyst too weakly, are ineffective  
23 for improving stereospecificity and are excluded from this  
24 invention.

25 Further increases in activity or stereospecificity  
26 may be obtained by premixing the transition metal component  
27 with either the amide or the alkyl metal, or both.

28 The amide effect is obtained with all the usual  
29 polymerization conditions. Thus solvent, temperature and  
30 monomer concentrations are not critical. Increased activity  
31 is obtained with all alpha olefins from ethylene to C<sub>10</sub> and  
32 higher as well as in copolymerizations such as ethylene/ $\alpha$ -  
33 olefin, ethylene/diolefin, propylene/ $\alpha$ -olefin, propylene/  
34 diolefin and ethylene/ $\alpha$ -olefin/diene copolymerizations. The  
35 amount of alkyl metal cocatalyst is usually in the range of  
36 0.1:1 to 20:1, preferably 0.5:1 to 10:1 mole ratio of

0015763

1 alkyl metal to transition metal compound. It is feasible  
2 using the hindered amides and hindered Lewis bases to employ  
3 higher mole ratios, up to 200:1 or higher, to achieve higher  
4 activity at high stereospecificity. The most preferred mole  
5 ratios with the hindered components is in the range 5:1 to  
6 200:1 alkyl metal plus amide to transition metal compound.

7 The concept of the invention can be restated as  
8 follows. Two types of alkyl metal compounds have been found  
9 to be effective for greatly increasing the activity of Ziegler  
10 catalysts, especially for propylene polymerization. These are  
11 alkyl aluminum dialkylamides and alkyl chloroaluminum dialkyl  
12 amides. The amides most preferably are sterically hindered.  
13 Both types are believed to operate by selectively scavenging  
14 the  $R'AlCl_2$  poison from the catalyst through the formation of  
15 mixed dimers. The dialkylaluminum additives are preferred  
16 because they regenerate the desirable  $R_2AlCl$  by reaction with  
17  $AlCl_2$ . However, the corresponding alkyl chloroaluminum amides  
18 are also effective additives for simply scavenging  $AlCl_2$ .  
19 These latter have the advantage over the dialkylaluminum types  
20 in that they have little, if any, polymerization activity so  
21 that the amounts used need not be so carefully controlled.

22 When the dialkylaluminum amide additives are used  
23 in excess over the amount of  $R'AlCl_2$  produced by the catalyst  
24 reactions, they are capable of forming active sites which  
25 yield lower isotacticity polymer. Therefore, these additives  
26 are preferably used in 5 to 50 mole % based on  $TiCl_3$ ,  
27 in the absence of extrinsic sources of  $R'AlCl_2$ . 50-100  
28 mole % should be used when added  $R'AlCl_2$  plus that formed by  
29 reacting  $R_2AlCl$  with  $AlCl_3$  in the titanium component is in  
30 the overall polymerization system. The best results are  
31 obtained when the molar amount of additive is approximately  
32 equal to the molar amount of  $R'AlCl_2$  produced before and  
33 during polymerization.

34 The alkyl groups on the aluminum compound containing  
35 2 to 12 carbons per alkyl group all produce higher  
36 activity catalysts. However, for propylene and higher alpha

1 olefins, polymer isotacticity decreases with increasing alkyl  
2 chain length. Therefore, C<sub>2</sub> to C<sub>4</sub> alkyl groups are preferred  
3 when isotactic polymers are desired.

4 The halide group in the aluminum components of the  
5 catalyst is preferably chloride or bromide, with chloride  
6 being most preferred.

7 The alkyl groups attached to the amide nitrogen are  
8 preferably attached to secondary or tertiary carbons to  
9 achieve sufficient steric hindrance. Primary alkyls are use-  
10 ful only when there is sufficient branching on the carbon atom  
11 beta or gamma to the nitrogen. Open chain as well as cyclic  
12 groups may be used. The most preferred groups are isopropyl,  
13 t-butyl and cyclohexyl groups.

14 The additives appear to be useful with any Group  
15 IVA-VIII Ziegler transition metal catalyst which produces  
16 R'AlCl<sub>2</sub> poison by reaction with aluminum alkyls. Trivalent  
17 titanium and vanadium chlorides are preferred with those  
18 having low aluminum content being most preferred. The addi-  
19 tives also appear to be generally useful for any monomer and  
20 mixtures of monomers.

21 When the dialkylaluminum amide additives are used  
22 in combination with aluminum trialkyl compounds, the preferred  
23 transition metal component is supported TiCl<sub>3</sub> or TiCl<sub>4</sub> on  
24 salts such as MgCl<sub>2</sub> or hydroxylchloride in which at least one  
25 Lewis base is also present. An excess of amide over the  
26 aluminum trialkyl may be used with supported TiCl<sub>4</sub> catalysts  
27 to further increase isotacticity. Thus the mole ratio  
28 of aluminum trialkyl to amide may be 1 to 50 to  
29 50 to 1, preferably 1 to 10 to 10 to 1. The molar  
30 ratio of the trialkyl metal compound to the supported transition  
31 metal compound is 0.5 to 1 to 200 to 1 or higher,  
32 more preferably 5 to 1 to 100 to 1. Lewis bases  
33 are normally added in less than stoichiometric amounts based  
34 on the trialkyl metal cocatalyst or the nitrogen-containing  
35 metal alkyl compound, preferably 0.1 to 1 to 1 to  
36 1. However, the hindered Lewis bases may be added in greater

1 than equimolar amounts, from 0.1 to 1 up to 10:1  
2 mole ratio, to obtain higher stereospecificity without a major  
3 loss of activity which would occur with unhindered bases.  
4

5 The advantages of the catalyst..  
6 system, the process for the alpha-olefin polymerization and  
7 the compositions of the mixed dimers of the  
8 present invention can be more readily appreciated by  
9 reference to the following Examples and tables.  
10 EXAMPLE 1

11 A series (A-G) of polymerization runs was carried  
12 out in a 1 liter baffled resin flask fitted with an efficient  
13 reflux condenser and a high speed stirrer. In a standard  
14 procedure for propylene polymerizations, 475 ml n-heptane  
15 (< 1 ppm water) containing 10 mmole  $\text{Et}_2\text{AlCl}$  (1.20 g) was  
16 charged to the reactor under dry  $\text{N}_2$  heated to reaction tem-  
17 perature (65°C) and saturated with pure propylene at 765 mm  
18 pressure. The  $\text{TiCl}_3$  (1.00 g) (6.5 mmole) was charged to a  
19 catalyst tube containing a stopcock and a rubber septum cap.  
20 Polymerization started when the  $\text{TiCl}_3$  was rinsed into the  
21 reactor with 25 ml n-heptane from a syringe. Propylene feed  
22 rate was adjusted to maintain an exit gas rate of 200-500  
23 cc/min at a pressure of 765 mm. After one hour at tempera-  
24 ture and pressure, the reactor slurry was poured into one  
25 liter isopropyl alcohol, stirred 2-4 hours, filtered, washed  
26 with alcohol and vacuum dried.

27 The  $\text{TiCl}_3$  was prepared by reduction of  $\text{TiCl}_4$  with  
28  $\text{Et}_2\text{AlCl}$  followed by treatment with diisopentyl ether and  
29  $\text{TiCl}_4$  under controlled conditions, yielding a high surface  
30 area delta  $\text{TiCl}_3$  having low aluminum content (hereinafter  
31 "low aluminum"  $\text{TiCl}_3$ ).

32 In Runs B-E, the diethyl aluminum diisopropylamide  
33 ( $\text{Et}_2\text{AlN(iPr)}_2$ ) was added to the reactor together with the  
34  $\text{Et}_2\text{AlCl}$ . The results summarized in Table I following show  
35 that activity increased sharply up to 1 mmole amide, then  
36 more slowly up to 3 mmoles amide. The percent heptane in-

1 solubles (also called isotacticity index) remained essen-  
2 tially constant, then decreased slightly at 3 mmoles amide.

3 Runs F and G show that still larger increases in  
4 activity are obtained by premixing the  $TiCl_3$  with either the  
5 amide or the  $Et_2AlCl$ .

6 Thus, the addition of only 5-30 mole % amide based  
7 on  $Et_2AlCl$ , or about 7-50 mole % based on  $TiCl_3$ , resulted in  
8 25-250 percent increase in polymerization rate over Control  
9 Run A.

10 The increased activity was not due simply to higher  
11 dialkyl aluminum concentration because 13 mmoles  $Et_2AlCl$  gave  
12 only 34.1 activity.

13

| 32 D          | 33 2                          | 34 51.8                     | 35 94.9                       |
| 36 E          | 37 3                          | 38 54.2                     | 39 92.0                       |
| F             | 2(b)                          | 65.2                        | 94.6                          |
| G             | 3(c)                          | 83.2                        | 91.7                          |

25 (a) Insoluble in boiling n-heptane based on total  
26 product, including alcohol-solubles minus catalyst.

27 (b) Mixed  $TiCl_3$  + amide in 12 ml n-heptane, 50°C. 15  
28 min. before charging to reactor containing the  
29  $Et_2AlCl$ .

30 (c) Mixed  $TiCl_3$  +  $Et_2AlCl$  in 10 ml n-heptane, 25°C. 30  
31 min. before charging to reactor containing the  
32  $Et_2AlN(iPr)_2$ .

33 The results as shown by the above data are that the  
34 technique of the invention can be used to more than double  
35 activity without a significant decrease in the heptane solu-  
36 bles of the resulting polymer.

37 EXAMPLE II

38 The procedure of Example I was repeated for addi-  
39 tional Runs H-N except that diethyl aluminum dicyclohexyl-

0015763

1 amide ( $E_2AlN(cycC_6)_2$ )<sub>2</sub> was used instead of the diisopropylamide.  
 2 Commercial delta cocrystallized  $TiCl_3 \cdot 0.33 AlCl_3$  (Stauffer AA  
 3 grade) (1.00 g) (5 mmoles) was used instead of  $TiCl_3$ . (This  
 4 commercial  $TiCl_3$  catalyst has lower activity than the "low-  
 5 aluminum  $TiCl_3$  catalyst" used in Example I). By "cocrystal-  
 6 lized" it is meant that the  $AlCl_3$  is an integral part of the  
 7 crystal lattice of the  $TiCl_3$ . The results are summarized as  
 8 follows in Table II.

TABLE II

## PROPYLENE POLYMERIZATION $\text{Et}_2\text{AlN}(\text{cyclo}\text{C}_6)_2$ Additive

| 14 | I           | 0.30  | 23.7                                  | 94.0                       |
| 15 | J           | 0.625   | 28.5                                  | 93.8                       |
| 16 | K           | 2   | 36.8                                  | 89.9                       |
| 17 | L           | 3   | 40.0                                  | 84.7                       |
| 18 | M           | 2(b)  | 32.3                                  | 93.0                       |
| 19 | N           | 2(c)  | 30.9                                  | 94.0                       |

(a) Same as (a) in Table I.

22 (b) Premixed  $TiCl_3 \cdot 0.33 AlCl_3$  + amide in 10 ml n-heptane,  
23 25°C, 30 min. before charging to reactor containing  
24 the  $Et_2AlCl$ .

25 (c) Premixed  $TiCl_3 \cdot 0.33 AlCl_3 + Et_2AlCl$  in 5 ml n-heptane,  
26 25°C, 30 min. before charging to reactor containing  
27 the  $Et_2AlN(cyC_6)_2$ .

28 The results in Table II show that activity nearly  
 29 doubled upon addition of 3 mmoles amide (60 mole % on  $TiCl_3$ ).  
 30 In contrast to the results in Example I using an essentially  
 31 aluminum-free  $TiCl_3$ , the polypropylene isotacticity decreased  
 32 substantially with increasing amounts of amide, but at least  
 33 a 40% increase of activity could be obtained without loss of  
 34 isotacticity.

35 Runs M and N show that premixing either the amide  
 36 or the  $\text{Et}_2\text{AlCl}$  with  $\text{TiCl}_3 \cdot 0.33 \text{ AlCl}_3$  resulted in a smaller  
 37 activity increase than was obtained without premixing (Run K),  
 38 but the heptane insolubles were raised back up to the Control

<sup>1</sup> (Run H). Thus, with premixing an approximately 60% increase  
<sup>2</sup> in activity could be obtained without loss of isotacticity.

### 3 EXAMPLE III

4 The procedure of Example II, Run K, was repeated  
5 except that 2 mmoles diethyl aluminum diethylamide was added  
6 instead of dicyclohexylamide. Polymerization rate was 24.9  
7 g/g  $TiCl_3 \cdot 0.33 AlCl_3$ /hr and heptane insolubles was 94.1 per-  
8 cent. Therefore, the unhindered diethylamide was much less  
9 effective than the hindered dicyclohexylamide in increasing  
10 catalyst activity.

## 11 EXAMPLE IV

12 The procedure of Example I, Runs B and D, was re-  
13 peated using diethyl aluminum dicyclohexylamide with similar  
14 results (40.3 and 47.6 g/g  $TiCl_3$ /hr vs 34.2 for the Control).

### 15 EXAMPLE V

16 The procedure of Example I, Run E was followed ex-  
 17 cept that brown  $TiCl_3$  (most beta) was used (prepared by mixing  
 18  $Et_2AlCl + TiCl_4$  in n-hexane at  $-30^\circ C$  and heating to  $65^\circ C$  for  
 19 1 hr, filtered, washed with n-hexane and vacuum dried). Poly-  
 20 merization rate increased to 41.4 g/g  $TiCl$ /hr from 18.0 for  
 21 the Control run performed in the absence of  $Et_2AlN(iPr)_2$ .

## 22 EXAMPLE VI

A titanium catalyst supported on  $MgCl_2$  was prepared by ball milling 20 g anhydrous  $MgCl_2$ , six ml ethylbenzoate and 3 ml methylpolysiloxane for 100 hr at room temperature. The solid was treated with an equimolar amount (based on  $MgCl_2$ ) of 1 M  $AlEt_3$  at 100°C for 1.5 hours, filtered and washed with heptane. This product was treated with excess 40%  $TiCl_4$  in heptane at 65°C, 2 hours, then with 90%  $TiCl_4$ , 65°C, 1.5 hours, washed thoroughly with heptane and vacuum dried, yielding a brown powder containing both  $TiCl_3$  and  $TiCl_4$ . The procedure of Example I, Runs A (Control) and D were followed except that 1 g of the supported catalyst was used in place of  $TiCl_3$ . Polymerization rate in the presence of amides increased to 75.7 from 21.1 in the  $Et_2AlCl$  Control. Heptane insolubles increased to 46.4 from 35.8.

1 EXAMPLE VII

2       Polymerization runs were made in a stirred auto-  
3 clave at 100 psi propylene pressure plus hydrogen for mol-  
4 ecular weight control using pentane diluent, 60°C, 2 hours.  
5 The Control run using 10 mmoles  $\text{Et}_2\text{AlCl}/5$  mmoles  $\text{TiCl}_3 \cdot 0.33$   
6  $\text{AlCl}_3$  (Stauffer AA grade) produced 495 g polypropylene/g  
7  $\text{TiCl}_3$ . Repeating the same run but also adding 2.5 mmoles  
8  $\text{Et}_2\text{AlN}(\text{iPr})_2$  increased catalyst efficiency to 612 g/g  $\text{TiCl}_3$ .

9 EXAMPLE VIII

10       Ethylene was polymerized following the procedure  
11 of Example I, Run A. During the first 25 minutes, the ethyl-  
12 ene absorption rate decreased from 370 cc/min to 330 cc/min.  
13 At this point, 3 mmoles  $\text{Et}_2\text{AlN}(\text{iPr})_2$  in 10 ml n-heptane was  
14 added. The ethylene absorption rate gradually increased to  
15 360 cc/min during the next 35 minutes. Thus, the rate of  
16 ethylene polymerization is also increased by the addition of  
17 a dialkylaluminum amide, but the effect is much smaller than  
18 for propylene polymerization.

19 EXAMPLE IX

20       An ethylene-propylene copolymerization was carried  
21 out in a similar manner to the procedure of Example VIII  
22 except that only 0.5 g  $\text{TiCl}_3$  plus 5 mmoles  $\text{Et}_2\text{AlCl}$  was used.  
23 The monomer feed rates were set at 150 cc/min ethylene and  
24 1350 cc/min propylene. During the first 20 minutes, the  
25 absorption rate was 550 cc/min. At this point, 1.5 mmoles  
26  $\text{Et}_2\text{AlN}(\text{iPr})_2$  in 10 ml n-heptane was added and the absorption  
27 rate increased to 750 cc/min for the next 15 min.

28 EXAMPLE X

29       The procedure of Example I was followed for a series  
30 of Runs T'-X' and AA except that halogenated aluminum amides  
31 were used together with various alkyl aluminum compounds. The  
32 preparation of low aluminum  $\text{TiCl}_3$  prepared by the technique  
33 described in Example I was used. The results are summarized  
34 as follows in Table IV.

TABLE IV

| 1  | 2       | 3 | Run                                    | Mmoles<br>BnAlX <sub>3-n</sub> | Mmoles<br>RXAlN(1Pr) <sub>2</sub> | Relative<br>Activity | % Heptane<br>Insoluble | 95.6 |

1

2 The data from these experiments show the following:

3 (1) Aluminum amides containing less than two alkyl  
4 groups are inactive alone (Run T) or when mixed with  $\text{RAlCl}_2$   
(Run U), because no  $\text{R}_2\text{AlCl}$  is present for active site formation.

5 (2) Alkyl chloroaluminum amides increase the activ-  
6 ity of catalysts containing  $\text{R}_2\text{AlCl}$  (Runs V', W' and BB).

7 (3) Long chain alkyl groups in the  $\text{R}_2\text{AlCl}$  component  
8 decrease heptane insolubles (Runs W' and X').

9 (4)  $\text{AlEt}_3$  yields very high activity in the presence  
10 of the amide (Run AA) but heptane insolubles are substantially  
11 less than in the  $\text{Et}_2\text{AlCl}$  control.

12 (5) Increasing the ratio of  $\text{Et}_2\text{AlCl}$ : amide from 5:5  
13 (Run V) to 10:2 (Run BB) gave no additional improvement in  
14 activity or heptane insolubles.

15 EXAMPLE XI

16 The procedure of Example I, Run B, was followed  
17 except that aluminum triethyl was used in combination with  
18 the diethyl aluminum diisopropylamide and the transition metal  
19 catalyst (0.2 g) was  $\text{TiCl}_4$  supported on  $\text{MgCl}_2$ . The catalyst  
20 was made by ball milling 5 moles  $\text{MgCl}_2$  with 1 mole ethyl-  
21 benzoate for one day, adding 1 mole  $\text{TiCl}_4$  and milling 3 days,  
22 then treating with neat  $\text{TiCl}_4$  at 80°C, 2 hours, washing with  
23 heptane and vacuum drying. The catalyst contained 3.44% Ti.

24 TABLE V

| 30 C          | 0   | 1  | 0                                   | --                                       |
| 31 D          | 0.25  | 1  | 20                                  | 96.8                                     |
| 32 E          | 1   | 3  | 267                                 | 90.4                                     |

33 The amide additive increased both activity and hep-  
34 tane insolubles with increasing concentrations (Runs A, B and  
35 E vs. control) although the amide was inactive alone (Run C).  
36 Keeping the amide concentration constant and decreasing the

1  $\text{AlEt}_3$  concentration (4 amide/1  $\text{AlEt}_3$ ) reduced activity but gave  
 2 very high heptane insolubles (Run D vs. Run B).

3 EXAMPLE XII

4 The procedure of Example XI was followed except that  
 5  $t\text{-Bu}_2\text{AlEt}$  was used instead of  $\text{AlEt}_3$ .

6 TABLE VI

| 7       | 8               | 9                            | 10     | 11   | 12   | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 | 32 | 33 | 34 | 35 | 36 | 37 | 38 | 39 | 40 | 41 | 42 | 43 | 44 | 45 | 46 | 47 | 48 | 49 | 50 | 51 | 52 | 53 | 54 | 55 | 56 | 57 | 58 | 59 | 60 | 61 | 62 | 63 | 64 | 65 | 66 | 67 | 68 | 69 | 70 | 71 | 72 | 73 | 74 | 75 | 76 | 77 | 78 | 79 | 80 | 81 | 82 | 83 | 84 | 85 | 86 | 87 | 88 | 89 | 90 | 91 | 92 | 93 | 94 | 95 | 96 | 97 | 98 | 99 | 100 |

1           These experiments show that small amounts of a Lewis  
 2 base added to the cocatalyst system result in a major improve-  
 3 ment in the stereospecificity while still retaining good  
 4 activity.

5           EXAMPLE XV

6           The procedure of Example XIV was followed except that  
 7 hindered amides and a highly hindered Lewis base were used.  
 8

TABLE VIII

| 9  | 10 | Run | Mmoles<br><u>AlEt<sub>3</sub></u> | Mmoles<br><u>Amide</u> | Mmoles<br><u>Amine (3)</u> | Rate | % HI |
|----|----|-----|-----------------------------------|------------------------|----------------------------|------|------|
| 11 | N  |     | 0.5                               | 1.5 A (1)              | 0.5                        | 169  | 98.1 |
| 12 | O  |     | 0.88                              | 3.12 B (2)             | 0.88                       | 343  | 98.4 |
| 13 | P  |     | 0.64                              | 1.36 B (2)             | 0.14                       | 387  | 95.8 |

14 (1) A = Et<sub>2</sub>AlN(cyC<sub>6</sub>H<sub>11</sub>)<sub>2</sub>

15 (2) B = Et<sub>2</sub>Al-2,2,6,6-tetramethylpiperidide

16 (3) Amine = 2,2,6,6-tetramethylpiperidine.

17           Comparison with the results in Table VII shows that  
 18 the combination of hindered amide and hindered amine increased  
 19 both activity and stereospecificity to higher levels than were  
 20 achieved with the unhindered amides and bases.

21           EXAMPLE XVI

22           The procedure of Example XV was followed except that  
 23 an unhindered Lewis base (ethylbenzoate = EB) was also added  
 24 together with the cocatalysts. A different preparation of sup-  
 25 ported catalyst was used which contained only 1.75% titanium.

TABLE IX

| 27 | 28      | Run | Mmoles<br><u>AlEt<sub>3</sub></u> | Mmoles<br><u>Amide (2)</u> | Mmoles<br><u>Amine (2)</u> | Mmoles<br><u>EE</u> | Rate | % HI |
|----|---------|-----|-----------------------------------|----------------------------|----------------------------|---------------------|------|------|
| 29 | Control |     | 0.4(1)                            | 0                          | 0                          | 0                   | 963  | 49.0 |
| 30 | Q       |     | 0.44                              | 1.56                       | 0.44                       | 0.2                 | .279 | 98.6 |

31 (1) 0.08 g. Catalyst

32 (2) B = Et<sub>2</sub>Al-2,2,6,6-tetramethylpiperidide.

33           The results in Run Q show that very high stereo-  
 34 specificity (98.6% heptane insolubles) was obtained by the  
 35 use of a dialkyl aluminum amide and two different Lewis bases

0015763

-18-

1 as modifiers for the trialkyl aluminum. The results are es-  
2 pecially striking since the control run shows that the cata-  
3 lyst gave very low stereospecificity (49% HI) in the ab-  
4 sence of cocatalyst modifiers.

5. EXAMPLE XVII

6                   The procedure of Example XIV, Run I, was followed  
7 except that a diarylamide, diethyl aluminum di-ortho-tolylamide,  
8 and a new preparation of the same type of supported catalyst  
9 which contained 3.38% Ti were used. The polymerization rate  
10 was 309 g/g. catalyst/hr. and the % HI = 93.4. Comparison with  
11 Example XIV control and Run I shows that the diarylamide was  
12 more effective than the diisopropylamide in increasing  
13 stereospecificity.

14 Since many modifications and variations of this  
15 invention may be made without departing from the spirit or  
16 scope of the invention thereof, it is not intended to limit  
17 the spirit or scope thereof to the specific examples thereof.

0015763

CLAIMS:

1. A catalyst composition which comprises a mixture of:
  - (a) at least one supported Group IVA to VIII transition metal halide;
  - (b) a trialkyl metal cocatalyst, said trialkyl metal cocatalyst having the structure  $R'^3Y$  wherein  $R'$  is a  $C_1$  to  $C_{20}$  primary alkyl, secondary alkyl, tertiary alkyl, neopentyl alkyl, branched alkyl, naphthenic or aralkyl group and  $Y$  is aluminium, gallium or indium;
  - (c) a nitrogen-containing metal alkyl compound having the structure  $R'^2YNR_2$  or  $R'XYNR_2$  wherein  $Y$  is Al, Ga or In,  $X$  is a halide and  $R'$  is a  $C_1$  to  $C_{20}$  primary alkyl, secondary alkyl, tertiary alkyl, neopentyl alkyl, branched alkyl, naphthenic or aralkyl group and  $R$  is  $C_3$  to  $C_{20}$  bulky alkyl, cycloalkyl, aryl or substituted aryl groups, with the proviso that the two  $R$  groups can be taken with  $N$  to form a pyrrolidyl or piperidyl and the alkyl substituted derivatives of pyrrolidyl and piperidyl, the mole ratio of said compound to said transition metal compound being from 0.5:1 to 200:1, and
  - (d) at least one Lewis base.
2. A composition according to claim 1 wherein  $Y$  is aluminium.
3. A composition according to either of claims 1 and 2 wherein said trialkyl metal cocatalyst is a trialkyl aluminium cocatalyst at a molar ratio of 1 to 50 to 50 to 1 based on said nitrogen containing metal alkyl compound.
4. A composition according to any one of the preceding claims wherein said nitrogen containing metal alkyl compound is diethylaluminium diisopropylamide, diethylaluminium dicyclohexylamide, diethylaluminium 2,2,6,6-tetramethylpiperidide or diethyl aluminium diorthotolyl amide.
5. A composition according to any one of the preceding claims wherein said transition metal compound is  $TiCl_3$  on a support or  $TiCl_4$  on a support.

0015763

6. A composition according to any one of the preceding claims wherein said support is  $MgCl_2$ .
7. A composition according to any one of the preceding claims wherein said Lewis base is an amine, ester, phosphine, ether, amide, sulfoxide, phosphine oxide, phosphate, phosphite, epoxide, saturated or unsaturated heterocycle, piperidine, pyrrolidine, ketone, tetrahydrofuran, secondary or tertiary aliphatic or aromatic amine.
8. A composition according to claim 7 wherein said Lewis base is ethyl benzoate.
9. A composition according to any one of claims 1 to 6 wherein said Lewis base is hindered.
10. A composition according to any one of the preceding claims wherein said R groups are aryl.
